

## Other galaxies

- Telescopic images of the night sky reveal many other galaxies
  - What do they look like?
    - ◆ are they all like the Milky Way?
  - Where are they?
    - ◆ spread randomly through space, or grouped?
  - What can we learn about the Universe?

Susan Cartwright

Our Evolving Universe

## A long time ago in a galaxy far, far away...

- How do we know these fuzzy blobs are distant galaxies?
  - some types of star (especially variable stars) have well-known intrinsic brightness
  - by measuring how bright they appear to be we can infer their distance
  - “*standard candles*”

Susan Cartwright

Our Evolving Universe

2

# Types of galaxies

- Galaxies seem to come in two basic types
  - smooth, featureless elliptical galaxies
    - ◆ circular or elongated
    - ◆ made of old, reddish stars
  - spiral galaxies like the Milky Way
    - ◆ some with round bulges, some with bars

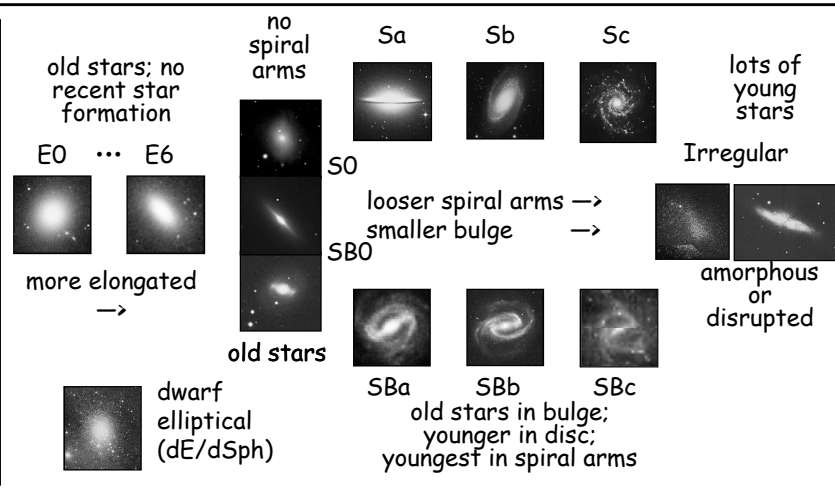

Susan Cartwright

Our Evolving Universe

3

# Hubble's tuning fork

Susan Cartwright

Our Evolving Universe

4

## Where do we fit in?

- The Milky Way is clearly not an elliptical galaxy
  - it has a disc, and contains young stars
- It has spiral arms
  - so, not S0
  - size of bulge and arm pattern suggest Sbc
    - ◆ between Sb and Sc
- There is evidence for a small bar
  - SBbc, or SABbc
    - ◆ SAB means intermediate between barred and unbarred

Susan Cartwright

Our Evolving Universe

5

## The Local Group

- The Milky Way is not alone: it is part of a small group containing
  - M31 (the Andromeda galaxy)
    - ◆ a large Sb spiral, bigger than us
  - M33
    - ◆ a small Sc spiral
  - the Large Magellanic Cloud
    - ◆ an irregular satellite of the Milky Way
  - at least 30 dwarf irregular and dwarf elliptical galaxies
  - but *no* large elliptical galaxies

Susan Cartwright

Our Evolving Universe

6

## Galaxy groups and clusters

- The Local Group is small: some rich clusters contain thousands of large galaxies
  - elliptical and S0/SB0 galaxies are much more common in rich clusters
  - spiral and irregular galaxies are much more common in small groups and the outskirts of clusters

## Galaxy properties

- |   |   |
|---|---|
| <ul style="list-style-type: none"> <li>■ Elliptical galaxies           <ul style="list-style-type: none"> <li>• contain old stars</li> <li>• have little net rotation               <ul style="list-style-type: none"> <li>◆ star orbits are randomly directed, as in our halo</li> </ul> </li> <li>• have little internal structure</li> <li>• are much more common in galaxy-rich environments</li> <li>• include the most massive galaxies (but also some with very low mass)</li> </ul> </li> </ul> | <ul style="list-style-type: none"> <li>■ Spiral galaxies           <ul style="list-style-type: none"> <li>• show recent star formation (in disc)</li> <li>• have rotating discs               <ul style="list-style-type: none"> <li>◆ stars all orbit in same direction</li> </ul> </li> <li>• have complex internal structure</li> <li>• are more common in low-density environments</li> <li>• have a smaller range of masses</li> </ul> </li> </ul> |
|---|---|

Lenticular (S0/SB0) galaxies are like spiral galaxies with no gas  
 Irregular galaxies are mostly like spirals too small to become organised

Our Evolving Universe

8

## Galaxy problems

- What makes some galaxies elliptical and others spiral?
  - their mass?
  - their age?
  - their rotation?
  - their history?
- How do spiral galaxies avoid "winding up" their spiral arms?
- How does the evolution of galaxies relate to the presence of central supermassive black holes?
  - the Milky Way's is, if anything, less massive than most!

Our Evolving Universe

9

## Galaxies and cosmology

- Almost all galaxies are moving away from us
  - and the greater their distance, the faster they recede (Hubble's law)
- Clusters of galaxies group to form huge superclusters, separated by vast voids
  - how does this large scale structure develop?
- What is the dark matter?
